Sticky traps baited with pheromones for *Dendroctonus rufipennis* were set up in the Klaipėda port and at the Vaidotai railway station alongside temporary stored timbers and in forests along roads in June–July 2000 (21 localities across the entire Lithuania); 111 beetle species and 6 genera were detected. Eight trophic groups of beetles were identified, and among them the largest number (38.7% of species detected and 28.5% of beetle specimens) presented a decaying wood and mycetobiont beetle group. Most frequent beetles were *Dasytes plumbeus* (Dasytidae), *Sciodrepoides watsoni* (Leiodidae) and *Polygraphus poligraphus* (Curculionidae). Scolytinae were represented by 5 species and 83 beetle specimens. No *D. rufipennis* was trapped. *Rhacopus sahlbergi* (Eucnemidae) and *Anobium nitidum* (Anobiidae) beetles were caught in two localities, and the species were ascertained as new for the Lithuanian fauna. There were detected 71 new localities with the occurrence of 54 beetle species rare for Lithuania.

Key words: bark beetles, sticky traps, rare Lithuanian species, new fauna species

INTRODUCTION

Wood is a very important material for many countries, and Lithuania is actively engaged in international wood trade. Economically significant insect species may be imported with wood from other parts of the world and cause undesirable consequences. It is necessary to organize the search in plant material imported to Lithuania in localities where timbers are temporarily stored (port and railway stations) or transported via roads close to forests. In early stages of insect invasion it is usually possible to eliminate the focus and to keep the costs of applied measures at a lower level. This investigation was one of the first attempts of the State Plant Protection Service to search for non-European bark beetles – *Dendroctonus rufipennis* after the establishing the Phytosanitary Research Laboratory in 1997. The hosts of *D. rufipennis* (Kirby) are *Picea* spp. (CAB 1997). Some tree species (*P. engelmannii*, *P. glauca*) that host *D. rufipennis* grow in Lithuanian parks, botanical gardens or plantations (Snarskis, Galinis, 1974; Januškevičius, 2004) and pose a

risk of introducing the species via international trade. Also, pheromones for *D. rufipennis* were established (Pitman, Vite, 1970; Vite et al., 1972; Kline et al., 1974; Furniss et al., 1976; Gries et al., 1992) and easily ordered. The goals of the present study were to test sticky (Cross-vane) traps for catching bark beetles (Curculionidae: Scolytinae), to perform the search for *D. rufipennis* in Lithuania and to examine the species composition of non-target insects in the traps.

MATERIALS AND METHODS

Sticky traps (Cross-vane traps, product code BC2590, AgriSense-BCS Ltd., former subsidiary of Thermo Trilogy Corporation, USA; Figure) and pheromone baits for *D. rufipennis* (lure, product code L085, AgriSense-BCS Ltd., former subsidiary of Thermo Trilogy Corporation, USA) were used. The pheromone bait was assumed to work for a period not shorter than a month. The traps were fastened to upper spruce branches 1.5 m above the ground at forest edges. The same height was used to hang the traps on stakes in localities where timbers were stored. The string, on which the traps

* Corresponding author. E-mail: vaathe@vaat.lt

were attached, allowed the traps to turn in all directions when the wind blew, so that flying beetles got sucked in and adhered to the glue. One trap per locality was used. Three localities were in the Klaipėda port (Klaipėda county), one nearby the Vaidotai railway station (Vilnius county), and the others along the roads in the following forests: Arvydai and Vievis (Vilnius county), Daugai and Druskininkai (Alytus county), Bubiai and Aukštelkai (Šiauliai county), Eičiai and Sakalinė (Tauragė county), Gražiškiai and Žalioji (Marijampolė county), Trimargis (Kaunas county), Rokiškis, Šilai and Žaliosios (Panevėžys county). In total, traps were set up in 21 localities during the period June 15 – July 31, 2000. Beetle specimens were removed from the glue with the help of a solvent (Heksan). Then beetles were washed in distilled water, dried and mounted. Species descriptions published in issues of Freude et al. (1966, 1967, 1969, 1971, 1974, 1976, 1979, 1981), Pileckis, Monsevičius (1995, 1997) were used for the trophic group determination. The nomenclature for beetles follows Silfverberg (2004). The index of dominance was calculated, and the classes of species were detected according to Durska (2001). The frequency of species (%) was calculated as a ratio of the number of localities where a species was recorded to the number of all the localities investigated.

RESULTS AND DISCUSSION

In total, 83 bark beetles of 5 species were caught; they represent a small number (7.8% of species) of the Scolytinae fauna known in Lithuania (Gaidienė, 1993; Silfverberg, 2004). *D. rufipennis* was not trapped. Also, a small number of entomophagi feeding on bark beetles were present. No *Rhizophagus*, especially *R. grandis* which feed on *Dendroctonus micans* larvae, were trapped. On the other hand, none of the European *D. micans* specimen was caught during the study. The latter is a rare species in Lithuania (Pileckis, Monsevičius, 1997), and the time used to trap adults was favourable.

In total, there were detected 8 trophic groups which comprised 111 beetle species and 6 genera (Table). The largest number (38.7% of species detected and 28.5% of beetle specimens) represented a decaying wood and mycetobiont beetle group. Among all trapped beetles, 2 new and 54 species rare for the Lithuanian fauna (the category after Pileckis, Monsevičius, 1995, 1997) were detected. The list of that with specified records (family, species, locality, date, number of trapped specimens) follows below (new species for Lithuanian fauna are marked with*).

CARABIDAE

Dromius agilis (F.); Šilai forest, block No 18, lot No 7, July 01–31, 2000; 1 sp.

Dromius quadraticollis Moraw.: Žalioji forest, block No 227, lot No 5, July 01–31, 2000; 2 sp.

LEIODIDAE

Anisotoma castanea (Hbst.): Arvydai forest, block No 4, June 26 – July 24, 2000, 1 sp.; Eičiai forest, block No 56, June 20 – July 29, 2000, 1 sp.

Agathidium seminulum (L.): Eičiai forest, block No 56, June 20 – July 29, 2000, 1 sp.

Ptomaphagus sericatus (Chaud.): Vaidotai railway station; June 15 – July 17, 2000, 1 sp.

Catops coracinus Kelln.: Sakalinė forest, block No 51, June 19 – July 28, 2000, 1 sp.

Catops morio (F.): Žalioji forest, block No 6, June 16 – July 24, 2000, 2 sp.; Žalioji forest, block No 227, lot No 5, July 01–31, 2000, 2 sp.; Šilai forest, block No 18, lot No 7, July 01–31, 2000, 2 sp.

STAPHYLINIDAE

Haploglossa gentilis (Märk): Bubiai forest, June 25 – July 30, 2000, 1 sp.

SCIRTIDAE

Scolytus rugulosus (Müll.): Žalioji forest, block No 227, lot No 5, July 01–31, 2000, 1 sp.

In total, we extended knowledge on the distribution of rare (54 species, 71 new localities) beetle species in Lithuania as compared to data known earlier (Pileckis, Monsevičius, 1995, 1997; Barševskis, 2001; Tamutis, Zolubas, 2001; Ferenca et al., 2002, 2006; Šablevičius, 2003, 2004; Tamutis, 2003; Ferenca, 2004; Inokaitis, 2004; Butvila et al., 2007; Ivinskis et al., 2009). To sum up the published (Pileckis, Monsevičius, 1995, 1997; Ferenca et al., 2002, 2006; Tamutis, 2003; Silfverberg, 2004; Ferenca, Tamutis, 2009) and our data, Lithuanian Anobiidae now comprise 33 species and Eucnemidae 8.

Table. The list of beetles caught in Cross-vane traps baited with pheromone for *Dendroctonus rufipennis* (Coleoptera: Curculionidae: Scolytinae) during June 16 – July 31, 2000 with class of dominance and frequency indexes

** Number of specimens, data not used to detect the class and frequency.

*** One specimen was trapped, and as it represent one species, data were used to detect the class and frequency.

Most frequent beetles were *Dasytes plumbeus* (Dasytidae), *Sciodrepoides watsoni* (Leiodidae) and *Polygraphus poligraphus* (Curculionidae). This corresponds with the species classes – eudominant and dominants – detected during our investigation (two more dominants – *Cychramus luteus*, *Cyphon ochraceus*). There were no control (traps with no pheromone bait), so it is impossible to confirm the attractivity of traps with baits for beetles. On the other hand, a very important point is the quantity of pheromone components or the ratio of a few components, which are usually distinct for different species (Jakaitis, 1988). Thus, all beetles caught during our investigation were ascertained as non-target.

A similar investigation in Lithuania, using cross-barrier traps baited with pheromone for *Ips typographus*, was made by other authors (Tamatit, Zolubas, 2001) during April–June of 1999. There were trapped 187 non-target beetle species belonging to 44 families. In comparison, our study indicates 1.7 times less non-target bark beetle species and 1.4 times specimens. Here differed investigation time and sites, better to test possibility of trapping when several type traps are disposed in a rank. It seems reasonable to catch a few trophic group representatives at the same time and to present a good part of decaying wood and mycetobiont beetle group when sticky (Cross-vane) traps are applied. A drawback of Cross-vane traps is that beetles stick to the glue, and it takes a longer time to mount them.

Figure. AgriSense-BCS Limited Cross-vane trap (consists of 2 interlocking plastic panels coated on both sides with non-drying glue)

CONCLUSIONS

1. In Lithuania, in 2000, using pheromone baits and traps for *Dendroctonus rufipennis*, no beetles of this species were recorded. Beetles of 111 species and 6 genera were trapped. Scolytinae were represented by 5 species and 83 specimens. Most frequent beetles were *Dasytes plumbeus* (Dasytidae), *Sciodrepoides watsoni* (Leiodidae) and *Polygraphus poligraphus* (Curculionidae).

2. Eight trophic groups of beetles were identified from sticky (Cross-vane) traps, among them the largest number (38.7% of species and 28.5% of specimens) represented the decaying wood and mycetobiont beetle group.

3. *Rhacopus sahlbergi* (Eucnemidae) and *Anobium nitidum* (Anobiidae) beetles were caught in two localities, and these species are new for Lithuanian fauna. There were revealed 71 new localities of the occurrence of 54 beetle species rare for Lithuania.

ACKNOWLEDGEMENTS

We are thankful to Dr. Vidmantas Monsevičius for the verification of Staphylinidae species and to specialists of the State Plant Protection Service for setting the traps.

Received 29 December 2009

Accepted 23 March 2010

VABALAI (COLEOPTERA), PAKLIUVĘ Į GAUDYKLĘS SU DENDROCTONUS RUFIPENNIS (KIRBY) (CURCULIONIDAE: SCOLYTINAE) FEROMONU, LIETUVOJE

S a n t r a u k a

Klijų (Cross-vane) gaudyklės su *Dendroctonus rufipennis* feromona buvo pakabintos Klaipėdos uoste ir Vaidotų geležinkelio stotyje prie laikinai sandėliuojamų rąstų bei miškuose prie kelių (visoje Lietuvoje 21 vietovė) 2000 metų birželį–liepą. Aptikta 111 rūšių ir 6 genčių vabalai. Nustatytos 8 trofinės sugautų vabalų grupės. Trūnijančios medienos ir micetobiontų grupės vabalai (38,7 % visų identifikuotų rūsių ir 28,5 % vabalų individų) sudarė didžiausią trofinę grupę. Dažniausiai vabalai buvo *Dasytes plumbeus* (Dasytidae), *Sciodrepoides watsoni* (Leiodidae) ir *Polygraphus poligraphus* (Curculionidae). Gaudyklėse nustatyti 5 rūsių 83 vabalai, priklaušantys Scolytinae pošeimiui, bet *D. rufipennis* vabalų neaptikta. *Rhacopus sahlbergi* (Eucnemidae) ir *Anobium nitidum* (Anobiidae) vabalai sugauti 2 vietovėse, ir šios rūšys papildė Lietuvos fauną. Žinias apie 54 retų Lietuvoje vabalų rūsių paplitimą papildė nauja 71 radavietė.

Raktažodžiai: kinivarpos, klijų gaudyklės, retosios Lietuvos rūšys, faunos naujos rūšys
